## ACKNOWLEDGEMENTS

We wish to convey our thanks to Dr.A.Laxmaiah, Dr.R.Hari Kumar and Dr.M.Vishnuvardhana Rao, Senior Research Officers; Dr.N.Arlappa, Mr.Ch.Gal Reddy, Mr.K.Mallikharjuna Rao, Dr.N.Balakrishna and Mr.B. Surya Prakasham, Research Officers; Mr.Sharad Kumar and Mr. M.Ravindranath, Technical Research Officers for their help during analysis.

We also thank Ms.G. Madhavi and other staff for their technical help and Mr. G.Hanumantha Rao and Ms. G. Prashanthi for their secretarial help.

Adolescence is a period of rapid growth and maturation in human development, after infancy. Since, there is very little information about dietary and nutritional status of adolescents in India, an assessment of the current diet and nutritional status of adolescents was carried out utilizing the data collected by the National Nutrition Monitoring Bureau (NNMB). In addition, the time trends in diet and nutritional status were determined. The anthropometric data obtained on 12,124 adolescents and 24 hour recall dietary information on 2,579 individuals in 1996-97 were analyzed and, were compared with the anthropometric data obtained on 24,683 adolescents and dietary information on 3,313 individuals obtained from the same villages in 1975-79.

The results revealed that the proportion of adolescent girls getting married before the age of 18 years was $23 \%$. Among them the proportion that could be considered as 'at risk' due to short stature ( $<145 \mathrm{cms}$ ) was $24.1 \%$ and that with under weight ( $<38 \mathrm{~kg}$ ) was $18.6 \%$. The food and nutrient intakes, in general, were below the RDA. More than two-thirds of adolescents were consuming <70\% RDA for vitamin A and riboflavin. The percent of underweight (<Median -2SD of NCHS weight for age) in males was $53 \%$ as compared to females (39.5\%). About 39\% were stunted.

The adolescents measured during 1996-97 were significantly taller and heavier than their counterparts studied in 1975-79 indicating secular changes in growth during a period of twenty years. There was an increase to the extent of 2.5 to 3.5 cms in mean heights and 1 to 1.5 kg in mean weights. In general, there was improvement in the nutrient intakes. The extent of severe deficit with respect to energy ( $<50 \%$ of RDA) decreased from $21 \%$ to $9 \%$ in boys and $14 \%$ to $5 \%$ in girls during 1996-97 as compared to 1975-79. The socio-economic variables like type of house, occupation and land holding and per capita monthly income were significantly ( $p<0.05$ ) associated with weight and height for age.

## 1. INTRODUCTION

Adolescence is a period of rapid growth and maturation in human development after infancy. The nutritional status of adolescent girls, the 'future mothers' contributes significantly to the nutritional status of the community. It is only recently that efforts, though small, are made to include adolescent girls as beneficiaries in some of the health and nutrition intervention programs.

There is very little information about dietary and nutritional status of adolescents in India. Hence, in this report, an assessment of the current diet and nutritional status of adolescents has been made utilizing the large data that was collected by the National Nutrition Monitoring Bureau (NNMB). In addition, the time trends in diet and nutritional status were determined by using the data that was collected by the NNMB in 1975-79 from the same villages.

The NNMB, through its annual surveys, since 1972, established a large database on different representative segments of population belonging to different States. It also conducted repeat surveys in 1988 and 1996 in the same villages that were surveyed in 1975-79. In the present report, results of analysis carried out on the data on adolescents collected during 1996-97 have been used to indicate the current status. These were compared with those obtained in 1975-79 to find out whether there were any time trends in the dietary pattern and nutritional status.

## 2. METHODS AND MATERIALS

### 2.1 SAMPLING DESIGN

### 2.1.1 Selection of villages

In the first repeat survey carried out during 1988-90, in each State about 100-120 villages were surveyed. Of these, $75 \%$ were those covered during 1975-79, while the remaining $25 \%$ were a new set of villages. A similar sampling procedure was adopted for the second repeat survey, covering 120 villages in each State. Of these, 90 villages were from those covered both in 1975-79 and 1988-90, while the remaining 30 villages were new. In each State, the villages were selected from 8 districts representing different geographic locations of the State. Thus, ninety villages were covered at all the three points of time and the 30 villages covered for the first time. The sampling design is presented in the following flow chart.

### 2.1.2 Selection of households

From each of the selected villages, 20 households (HHs) were selected by adopting 'cluster sampling method'. For this purpose, the main village and its hamlets (if any) were divided into 5 natural clusters, consisting of groups of houses/streets/ mohallas/areas, which included at least one cluster inhabited by SC/ST community. From each of the selected clusters, 4 consecutive households were surveyed, by selecting the first household randomly.

If the number of households in a given cluster was too large, the cluster was further divided into sub-areas, and one sub area was selected randomly for covering 4 HHs. Thus, in each State, a total of 2400 HHs were targeted for survey.

HH auo : Kanuns łə!p əxełu! ןenp!^!pul

 NפISヨG SNITdW甘S

### 2.2 INVESTIGATIONS

The following investigations were carried out in the selected HHs.

### 2.2.1 Household Particulars

Demographic and socio-economic particulars such as age, sex, occupation, literacy level, family income, possession of agricultural land and live stock, type of dwelling etc. of all the household members were collected, by administering an household schedule in all the households.

### 2.2.2 Nutrition Assessment

In each village, all the 20 selected HHs, were covered for nutrition assessment. Anthropometric measurements like height, weight, arm circumference and fat fold at triceps were taken on all the available members of the households, using standard equipment and procedures ${ }^{1}$. They were also examined for the presence of clinical signs of nutritional deficiencies.

### 2.2.3 Diet Survey

Diet survey was conducted in every alternate HH ( 10 HHs ) covered for nutrition assessment. While one-day weighment diet survey was conducted in 5 HHs to assess intakes at the household level, 24 -hour recall method of diet survey ${ }^{2}$ was conducted in the rest of the households, to assess individual intakes. The following Table presents the number of HHs covered for different investigations in each selected village and the total sample covered for various activities.

| Method of Survey | No. of HHs <br> Covered |
| :--- | :---: |
| Household socioeconomic profile, <br> Anthropometry \& Clinical Examination | 20 |
| Household diet survey | 5 |
| Individual diet Survey | 5 |

### 2.3 ANALYSIS

### 2.3.1 Food and Nutrient Intake of Individuals

The average daily food and nutrient intakes of different physiological groups in the households surveyed were computed. The nutrient intakes were calculated using the values given in Nutritive Value of Indian Foods ${ }^{4}$. The food intakes were compared with the levels recommended in balanced diets for Indians $(1981)^{5}$, whereas the average intakes of nutrients were compared with the levels suggested in Nutrient requirements and Recommended Dietary Allowances (RDA) for Indians (1990) ${ }^{3}$.

### 2.3.2 Anthropometry

Mean heights and weights were calculated according to age and sex. The distance charts for height and weights were compared at both the points of surveys, as well as with those of the National Centre for Health Statistics (NCHS) standards ${ }^{6}$.

### 2.3.2.1 SD Classification

Recently, large scale national surveys like National Family Health Survey $(1993)^{7}$ have adopted Standard Deviation classification ${ }^{8}$ for assessing undernutrition. Therefore, for the purpose of comparison, the percent distribution of adolescents was calculated using NCHS reference values for weight for age to assess undernutrition, and 'height for age', to assess the extent of stunting. Details of the SD classification are given below:

| Cut-off level | Nutritional Status |  |
| :---: | :--- | :---: |
|  | Weight for age | Height for age |
| >Median-2SD | Normal | Normal |
| Median-2SD to <br> Median-3SD | Moderate <br> undernutrition | Moderate stunting |
| <Median -3SD | Severe <br> undernutrition | Severe stunting |

## 3. RESULTS

The anthropometric data obtained on 12,124 adolescents and 24 hour recall dietary information on 2,579 individuals in 1996-97 were analyzed to assess (i) the diet and nutritional status of adolescents from eight States, and (ii) the role of socioeconomic factors on nutritional status. These results were compared with the anthropometric data obtained on 24,683 adolescents and dietary information on 3,313 individuals obtained from the same villages in 1975-79. The distribution of the sample covered in different States is presented in Table-1.

### 3.1 CURRENT DIETARY AND NUTRITIONAL STATUS

### 3.1.1 Profile of the sample surveyed

The coverage of children by sex for anthropometry and diet survey is given in -Table-2\&3. The socio-economic and demographic profile of the sample covered is given in Table-4. Majority of them ( $90.8 \%$ ) belonged to Hindu religion, while about $27 \%$ belonged to scheduled caste community. About $30 \%$ belonged to backward communities and about $12 \%$ were from scheduled tribes. In general, the families
were large with over $77 \%$ belonging to families with 5-10 family members. About $42 \%$ of the heads of the households were illiterate.

Almost all the adolescents (97.9\%) were residing in their own houses. About $61 \%$ of the houses were kutcha as compared to $8.1 \%$ pucca houses. More than a third (37.3\%) of the households did not possess any land. The major occupation was agriculture with most of the families belonging to either labourers (27\%) or tenant/owner cultivators (45.5\%). The mean per capita income (PCI) per month of the household was about Rs.250/- at 1996-97 prices. Per capita income of different quartiles was also calculated. It was interesting to note that while the Mean PCl in the lowest quartile was Rs.77/-, in the highest quartile group, it was Rs.626/- indicating the wide variations in the socio-economic status of the rural households.

### 3.1.2 Marital Status

One of the risk factors among adolescent girls is early marriage causing early cessation of growth leading to birth of low birth weight baby. The proportion of adolescent girls getting married before the legal age of 18 years was $23 \%$. Among the married adolescent girls, the proportion of the girls considered 'at risk' due to short stature ( $<145 \mathrm{cms}$ ) was $24.1 \%$ and under weight ( $<38 \mathrm{~kg}$ ) was $18.6 \%$. In other words, these adolescent girls could be considered as at risk ${ }^{9}$ in terms of pregnancy outcome.

### 3.1.3 Nutritional Anthropometry

### 3.1.3.1 Mean Anthropometric measurements

The mean and median anthropometric measurements of adolescent children are presented in Table-5. Distance charts for heights and weights by sex are presented in Fig. 1. The girls overtook boys at about 11 years and the boys over took the girls at about 13 years, after which the boys were significantly taller than girls $-(\mathrm{P}<0.01)$. In other words, in the case of the girls, the puberty started about 2 years earlier than the boys. At the age of 17 years, the girls were shorter in height than the boys by about 10 cms and weighed 3 kgs less. At all ages, the adolescents were shorter and lighter than their American counterparts (NCHS).

|  | Median | 159.6 | 161.5 | 43.2 | 45.8 | 150.1 | 152.5 | 40.6 | 42.8 |

### 3.1.3.2 SD Classification

The adolescents were categorized into different grades of nutritional status, based on weight for age and height for age by SD classification using NCHS Standards. All those children with weight for age / height for age equal to or more than Median - 2SD were taken as normal, those with Median - 2SD to Median 3SD as moderately undernourished and all those with <Median - 3SD were taken as severely undernourished.

## Stunting

The $Z$ analysis of data indicated that the over all prevalence of stunting (<Median height -2SD) was similar in both the sexes (boys: $39.5 \%$ and girls: $39.1 \%$ ). The percentage of stunting increased as the age advanced in boys from $34.7 \%$ at 10 years to $59.7 \%$ at 17 years. In the case of girls, the percentage of stunting increased with increasing age ( $32.5 \%$ to $46.7 \%$ ) up to 13 years after which it decreased to $37.2 \%$ at the age of 17 years (Table-6).

## Underweight

In case of body weights, the percent of undernutrition (<Median -2SD of NCHS weight for age) in males was $53.1 \%$ as compared to females (39.5\%). As in the case of height, the percent Of boys with undernutrition increased from $41.6 \%$ at 10 years to $68.6 \%$ at 17 years, while in girls, the extent of under nutrition increased ( $37.8 \%$ to $45.3 \%$ ) till the age of 12 years and plateaued at $39.0 \%$ in the later age groups (Table-6).

Table 6 Per cent Distribution of Adolescents According to Stunting and Underweight

| Age <br> (Yrs) | Boys |  | Girls |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Stunting <br> (Height for Age <br> <Median-2SD) | Underweight <br> (Weight for Age <br> <Median -2SD) | Stunting <br> (Height for Age <br> <Median-2SD) | Underweight <br> (Weight for Age <br> <Median -2SD) |
| $10+$ | 34.7 | 41.6 | 32.5 | 37.8 |
| $11+$ | 31.2 | 42.1 | 37.4 | 42.4 |
| $12+$ | 32.8 | 51.6 | 44.7 | 45.3 |
| $13+$ | 32.1 | 51.2 | 46.7 | 37.6 |
| $14+$ | 36.3 | 55.8 | 41.2 | 35.7 |
| $15+$ | 48.9 | 58.5 | 37.9 | 39.0 |
| $16+$ | 51.8 | 66.1 | 34.1 | 39.0 |
| $17+$ | 59.7 | 68.6 | 37.2 | 37.6 |
| $x^{2}$ | $223.85(\mathrm{P}<0.01)$ | $195.8(\mathrm{P}<0.01)$ | $60.9(\mathrm{P}<0.01)$ | $23.3(\mathrm{P}<0.01)$ |

## ANTHROPOMETRY

- The proportion of stunted increased with increasing of age.
- The percent of undernutrition was higher in boys than in girls.

## Body Mass index

It is well known that Body Mass Index (BMI) is not constant with age in growing children. Hence, medians of BMI were calculated to assess the differences between ages (Table-7). These BMI values for age and sex were compared with those reported for NHANES survey in USA. The proportion of adolescents below the $5^{\text {th }}$ percentile of NHANES ranged from $44 \%$ in 17 years age group to $77.6 \%$ in 11 years among boys and from $16.4 \%$ in 17 years to $62.7 \%$ in 10 years among girls. However, the extent of undernutrition was considerably less among girls than their male counterparts in each of the age groups (Table-8).

Table 7 Median Body Mass Index of Adolescents

### 3.2 FOOD AND NUTRIENT INTAKE

The Mean daily intakes of different foods of adolescents according to age and sex are presented in Tables-9 \& 10.

The mean intakes of all the nutrients were below the RDA in all the age groups of adolescents irrespective of sex. (Tables-11,12 \& 13)

In order to assess the extent of severity of food deficit, the nutrient intakes were expressed as \% of RDA and the distribution of adolescents consuming <50\% and $<70 \%$ of RDA was calculated for both the sexes (Table-14). In general, in both the sexes, the proportion of adolescents consuming inadequate amounts was higher in case of micronutrients than that of protein, energy and total fat. More than twothirds of adolescents were consuming $<70 \%$ RDA for vitamin A and riboflavin. It was interesting to note that because of higher RDA in boys, the extent of deficiency with respect to iron was higher than in girls.

## NUTRIENT INTAKES

- Median nutrient intakes were below the RDA.
- About 60-80 \% of adolescents consumed micronutrients $<70 \%$ of RDA.

### 3.3 TIME TRENDS

As indicated earlier, the changes in the diet and nutritional status, if any, were assessed by comparing the data collected during 1975-79 and 1996-97.

### 3.3.1 Secular trends in growth

Distance charts for height and weight for each sex according to period of survey are presented in Figs. 2 and 3. The adolescents measured during 1996-97 were significantly taller and heavier than their counterparts studied in 1975-79 indicating secular changes in growth during a period of twenty years. There was an increase to the extent of 2.5 to 3.5 cm and 1 to 1.5 kg , which was statistically significant ( $\mathrm{P}<0.05$ ).

### 3.3.2 Nutrient Intakes

The distribution of children according to intakes expressed as \% RDA (<70\% and $<50 \%$ of RDA) at both the points of time indicates that in the case of most of the nutrients there was reduction in the proportion of adolescents having deficient dietary intakes over the last two decades. The extent of severe deficit with respect to energy ( $<50 \%$ of RDA) decreased from $21 \%$ to $9 \%$ in boys and $14 \%$ to $5 \%$ in girls in 1996-97 as compared to 1975-79. The extent of decline in case of Iron and vitamin 'A' was less as compared to other nutrients. In other words, in general, there was improvement in the nutrient intakes (Table-14; Figs. 4 to 7) over a period of two decades.

Table 14 Distribution (\%) of Adolescents according to Intake of Nutrients as \% of RDA

| Nutrients | Percent <br> RDA | Boys |  | Girls |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  | Protein |  | $<50$ | $7975-79$ | $1996-97$ |
| Total Fat | $<70$ | 23.4 | $1975-79$ | $1996-97$ |  |
|  | $<50$ | 32.3 | 12.9 | 25.2 | 18.2 |

Fig-7.
PERCENT DISTRIBUTION OF ADOLESCENTS WITH IRON INTAKE OF <RDI

## Food and Nutrient Intake

- Cereal intake increased over period in all ages.
- Intakes of income elastic foods such as fish, fruits, milk, fats \& oils and sugar increased in all ages.
- Intakes of all the nutrients except thiamin increased in all the ages in both sexes.

## Anthropometry

- Adolescents in 1996-97 were significantly taller and heavier than their counternarts in 1975-79.

### 3.3.3 Socio-economic factors and dietary and nutritional status

The association between various demographic and socio-economic on one hand and anthropometric parameters on the other was studied. For the purpose, standard deviation classification of height/age and weight/age were used. For assessing the significance of relationships of each variable ${ }^{\chi^{2}}$ test was used. The adolescents were divided into two groups of normal (Median-2SD) and undernourished (<Median -2SD).

The variables like religion, community, type of family, literacy status, type of house, land holdings, occupation and per capita income were significantly associated with the nutritional status as assessed by height/age ( $\mathrm{P}<0.05$ ) (Table-15). The extent of stunting in Christians was marginally less (31.8\%) than among Hindus (39.4\%), and those of SC community ( $42.7 \%$ ). The adolescents belonging to extended family had lower prevalence of stunting (34.6\%) as compared to those belonging to joint family (42.0\%).

The percentage of stunting among adolescents was higher in those living in kutcha houses (40.5\%) than those living in pucca houses (31.8\%). The extent of stunting was higher in labourer families (40.3\%). The extent of stunting decreased with increasing size of land holdings. The prevalence of stunting among adolescents decreased with increasing per capita income.

All the demographic variables like religion, community, type of family, family size, literacy status, type of house, land holdings, occupation and per capita income were significantly associated with weight/age ( $\mathrm{P}<0.05$ ) (Table-15). The percentage of undernutrition was higher among Hindus (46.2\%) and those from ST community. On the other hand, among the adolescents belonging to extended family, the percentage of undernutrition was less ( $40.7 \%$ ) as compared to joint family ( $48.6 \%$ ). The adolescents of literate head of the household had lower undernutrition.

The extent of undernutrition was higher among those living in kutcha houses; involved in agriculture labour, among the landless and those with lower PCI.

## SOCIO ECONOMIC V/s NUTRITION STATUS

- Extent of stunting was significantly higher in SC community.
- Prevalence of undernutrition was higher among ST community.
[] Proportions of stunted were higher, in adolescents living in kutcha houses.

0. The proportion of stunted and undernourished children was higher in the households with low per capita income.

## 4. COMMENTS

The nutritional status of adolescent girls, the 'future mothers' contributes significantly to the nutritional status of the community. An assessment of the current diet and nutritional status of adolescents was made utilizing the large data collected by the National Nutrition Monitoring Bureau (NNMB). In addition, the time trends in diet and nutritional status were determined by comparing with the data that was collected by the NNMB in 1975-79 from the same villages. Most of the adolescents belonged to families involved in agriculture with a per capita income of about Rs. 250.

About $23 \%$ of adolescent girls were married before the legal age of 18 years. Among the married adolescent girls, about 19-24\% of adolescent girls could be considered as 'at risk' because of either short stature or underweight. Undernutrition (<Median -2SD of NCHS weight for age) was widespread both in males (53.1\%) and females (39.5\%). The prevalence of stunting (<Median height -2SD) in both the sexes was similar (boys: $39.5 \%$ and girls: $39.1 \%$ ).

The proportion of adolescents below the $5^{\text {th }}$ percentile of NHANES-BMI ranged from $44 \%$ in 17 years of age to $78 \%$ in 11 years among boys and from $16 \%$ in 17 years to $63 \%$ in 10 years among girls. However, the extent of thinness was considerably less among girls as compared to their male counterparts. The mean intakes of all the nutrients were below the RDA in all the age groups of adolescents irrespective of sex. In general,Xin both the sexes, about two-thirds of adolescents were consuming inadequate amounts of micronutrients. Perhaps, because of higher RDA, the extent of dietary deficiency in iron was higher in boys than in girls. There was improvement in the nutrient intakes in 1996-97 as compared to 1975-79. The extent of severe deficit with respect to energy ( $<50 \%$ of RDA) decreased from $21 \%$ to $9 \%$ in boys and $14 \%$ to $5 \%$ in girls during 1975-79 to 1996-97. The adolescents measured during 1996-97 were significantly taller and heavier than their counterparts studied about two decades back indicating secular changes in growth during a period of twenty years. There was an increase to the extent of 2.5 to 3.5 cm in height and 1 to 1.5 kg in weight.

## ACKNOWLEDGEMENTS

We wish to convey our thanks to Dr.A. Laxmaiah, Dr.R.Hari Kumar and Dr.M.Vishnuvardhana Rao, Senior Research Officers; Mr.Ch.Gal Reddy, Mr.KMallikharjuna Rao, and Mr.B.Surya Prakasham, Research Officers; Mr. M.Ravindranath, Technical Research Officer and Ms.M.Uma Nayak and Ms.K.Damayanthi, Nutritionists for their help during analysis.

We also thank Mr.P.Satish Babu, Mr.G.Govinda Rajulu, Ms. K. Shyamala, Ms.Vani Vijayaratnam, Ms.G.Madhavi and other staff for their technical help. Our thanks are also due to Mr. G. Hanumantha Rao and Ms. G. Prashanthi for their secretarial help.

Aging is one of the important developments of the $20^{\text {th }}$ century. The present aged population in India is about 56 million (6.7\%). There is dearth of comprehensive information on the nutritional status of elderly. This report presents the results based on the current status of the elderly population using the available large data collected in different states of the country by the National Nutrition Monitoring Bureau (NNMB). The objectives were to assess the current status of diet and nutritional status of elderly population and the time trends if any, in their diet and nutritional status over two decades.

About 922 elderly individuals were covered for diet survey and 3646 for anthropometric measurements during 1996-97, while the coverage was 858 and 3659 respectively for the period during 1975-79. The mean intakes of cereals and millets together are 445 g and 357 g in males and females respectively. The consumption of pulses, GLV and other vegetables was less than RDI in both the sexes. The mean intake of Milk and Milk Products was below the RDI. The mean and median intake of protein was slightly below the RDI in both the sexes. The mean intakes of energy for male and females are 2167 and 1764 kcals. About 65\% elderly population consumed more than the RDI of energy. In the case of vitamin $A$ and riboflavin, the intakes were below the RDI. In about 59\%, the intakes of Vit.A were less than $30 \%$ of RDI and only $13 \%$ consumed more than the RDI. ProteinCalorie adequacy status was observed in large proportion of elderly (male: $90 \%$ and female: 67\%).

The prevalence of Chronic Energy Deficiency (CED) (BMI <18.5) was relatively more among males (53.5\%) than in females (49.4\%). The prevalence of overweight/obesity ( $B M 1>25.0$ ) was $4.2 \%$ in males, and $7.7 \%$ in females. The mean intakes of cereals \& millets, GLV, other vegetables, nuts \& oils, milk \& milk products and sugar \& Jaggery were higher in 1996-97 than those of 1975-79. The median intakes of nutrients among the elderly were higher in 1996-97 than of 1975-79. The median intakes of most of the nutrients, except iron and niacin were statistically significantly different between periods ( $p<0.05$ ). A comparison between periods revealed that the extent of CED declined from about 62.3\% in 1975-79 to 53.5\% in 1996-97 among males and from 63.8\% to $49.4 \%$ among females. An increasing trend was observed in the proportion of normal, overweight and obesity between 1975-79 and 1996-97.

## 1. INTRODUCTION

The twentieth century has seen an unprecedented transition from high birth and death rates to low fertility and mortality rates ${ }^{1}$, resulting in increased longevity. Thus, aging of the population is one of the important developments of the $20^{\text {th }}$ century during which there has been a considerable increase both in absolute and relative numbers of older people (60 years and above) in both developed and developing countries ${ }^{2}$. This new development could be attributed to decline in the mortality rates due to improved health care facilities, changed life styles and diversification of food habits.

According to the UN estimates ${ }^{2}$, the elderly population was about 350 million in 1975. The projected figures for the years 2000 and 2025 are 590 and 1,100 million respectively. Currently, it is estimated that there are about 580 million elderly people in the world, of whom 355 million are in the developing countries. By the year 2020, it is estimated that there will be more than 700 million elderly people in the developing world ${ }^{2}$. In India, the present population of elderly is about 56 million ( $6.7 \%$ ). In 20 years time, the number is expected to increase to 158 million, constituting roughly 8 9 per cent of the total population ${ }^{2}$.

The increased proportion of aged population, due to higher life expectancy, is not necessarily devoid of any problems, and, in fact it invites a lot of socio-economic, psychological, physiological and health and nutritional problems. Hence, the health of the elderly has been attracting the attention of the medical professionals, psychologists, social scientists, nutritionists and governmental and non-governmental organizations all over the world. Adequate, appropriate and sufficient nutrition is essential to the health and well being of elderly. Generally the elderly people are nutritionally most vulnerable, the primarily due to poor dietary intake. Other factors, which contribute to undernutrition among the aged, are decreased physical activity, mental depression mostly due to isolation, maldistribution of food, poor eating habits, chronic ill health and dental problems.

In India, there is dearth of comprehensive information on the nutritional status of elderly. There is, therefore, a need to develop database on the diet and nutritional status of the elderly from different parts of the country to enable the Government and NGOs to formulate policies and initiate strategies, which would contribute to the well being of elderly population. In this report, an attempt has been made to assess the current status of the elderly population using the available large data collected in different states of the country by the National Nutrition Monitoring Bureau (NNMB) during 1996-97.

### 1.1 OBJECTIVES

1. To assess the current status of diet and nutritional status of elderly population in eight states where NNMB has been collecting information annually.
2. To assess time trends, if any, in their diet and nutritional status during the last two decades.

## 2. MATERIALS AND METHODS

The NNMB has been carrying out annual diet and nutrition surveys since 1972. The data collected during 1996-97 by the NNMB on diet and nutritional in the rural areas of Kerala, Tamil Nadu, Karnataka, Andhra Pradesh, Maharashtra, Madhya Pradesh, Gujarat, Orissa has been utilized to asses the current nutritional status of elderly ${ }^{3}$. In addition, to assess the time trends, data collected during 197579 in the same villages was utilized.

### 2.1 SAMPLING DESIGN

### 2.1.1 Selection of villages

The NNMB surveyed 120 villages in each state, 90 of which were those surveyed during 1975-79 and 30 were newly selected villages. The sample was so selected as to represent the dietary and nutritional status at the state level.

### 2.1.2 Selection of households

From each of the selected villages, 20 households were selected by adopting cluster-sampling method. For this purpose, the main village and its hamlets, if any, were divided into five natural clusters consisting of groups of houses/streets/bastis/ mohallas/areas, of which SC community inhabited one cluster. From each of the clusters, 4 consecutive households were surveyed by selecting the first household randomly. Of the 20 HHs , ten were selected for diet survey. Of those 5 were selected for one day household weighment diet survey and remaining 5 HHs were selected for 24 hour dietary recall on all the members of the HH

### 2.1.3 Information

The following information has been used:

1. Socio-economic and demographic profile of the HHs and the individuals surveyed.
2. Diet survey of individuals by 24 dietary recall.
3. Anthropometric data on height, body weight, MUAC and FFT and
4. Clinical nutrition profile.

### 2.2 Statistical Analysis

Statistical analysis was performed using SPSS 7.5 windows version. The data was analyzed by dividing the elderly into the following three specific age groups:

- 60-69 years
- 70-79 years
- $\geq 80$ years

Mean and SD values of food intakes and mean, median and SD values of nutrient consumption were calculated according to age, sex and the periods of survey. Mean, median and SD's of anthropometric measurements for the three age groups were calculated. Comparison of mean values of food and nutrient intakes were tested by ANOVA ' $F$ ' test with multiple comparison procedure and non parametric test of Kruskal Wallis one way ANOVA were utilized, whenever the assumption of homogeneity of variance was violated. Median test was used for comparison of medians between two periods for nutrients.

The results were compared with that of the adults below the age of 60 years (i.e. non-elderly adults). The time trends over period were assessed by comparing the data collected in 1996-97 with that collected during 1975-79.

Prevalence rates of chronic energy deficiency (CED) were calculated using Body Mass Index (BMI). BMI is the ratio between weight in kg and the square of height in metres. Association of BMI, food and nutrient intakes with socio economic parameters was analyzed with chi-square test.

## 3. RESULTS AND DISCUSSION

About 922 elderly individuals were covered for diet survey and 3646 for anthropometric measurements during 1996-97, while the coverage was 858 and 3659 respectively for the period during 1975-79 (Table 1).

Table 1 SAMPLE COVERAGE

| Details | Year of <br> study | Age in Years |  |  |  |  |  |  |

### 3.1 SOCIO ECONOMIC PROFILE

The details of socioeconomic status of the population surveyed in 1996-97 are presented in Table 2.

### 3.1.1 Religion

Majority of households of the elderly surveyed belonged to Hindu Religion (81.6\%), while the rest were Christians (5.3\%), Muslims (4\%) and others (9.1\%).

### 3.1.2Community

About 29\% belonged to SC and ST population, while the rest belonged to other communities.

### 3.1.3Type of House

About 47.4\% of the houses were kutcha and the rest were semi pucca (39.0\%) or pucca (13.6\%).

### 3.1.4Type of Family

About 75\% of the households were nuclear or extended nuclear families, while the rest of $25 \%$ were joint families .

### 3.1.5 Major Occupation of Head of Household

Agriculture was the major occupation of a majority of the households. About 39\% of the households were engaged in agriculture, while about $21 \%$ were either agricultural labourers or other labourers.

### 3.1.6 Landholdings

A majority of the households belonged to either landless (39\%) or small farmers having less than 5 acres (45\%).

### 3.1.7 Family Size

About $30 \%$ of the elderly belonged to HHs having < 4 members, $26 \%$ of the HH had $\geq 7$.

### 3.1.8 Literacy Status

About $65.6 \%$ of heads of the HH s were illiterates.
Table 2 SOCIO ECONOMIC PROFILE

| Variable | Categories | $\%$ |
| :---: | :---: | :---: |
| Community | SC+ST | 29.2 |
|  | Others | 70.8 |

### 3.2 DIETARY CONSUMPTION

### 3.2.1 Foods

The consumption of foodstuffs (g/day) according to age and sex is presented in Tables 3 and 4 \& Fig. 1.

The cereals and millets formed the bulk of dietaries of the elderly, as in other age groups. The intake of cereals and millets in males were 338 g and 107 g respectively, whereas in females, the intakes were 291 g and 66 g respectively.

The variation in dietary intake was large. Mean intakes of cereals and millets together were more than RDI. (Males: 445 g and Females: 357 g ). In all the age groups and in both the sexes, the consumption of cereals and millets was above the $\mathrm{RDI}^{5}$. The cereal intake was considerably reduced in oldest age group of $\geq 80$ years.

The mean intake of pulses in male and female was 31 g and 27 g respectively. The consumption of pulses and green leafy vegetables was less than RDI in all age groups in both the sexes.

The intake of other vegetables, though was better than that of green leafy vegetables in all the age groups in both the sexes, was still lower than the RDI. The elderly males consumed higher than the suggested level of ( 50 g ) of roots and tubers in all age groups. Mean intakes of sugar \& Jaggery for males and females were 25 g and 21 g respectively.

### 3.2.2 Nutrients

The mean and median intakes of nutrients, calculated for three age groups and sexes, are presented in Tables 5 \& 6 and are compared with RDI values suggested by the Expert Committee of ICMR ${ }^{4.5}(1990)$ (Fig.2).

The mean and median intakes of protein were slightly less than the RDI in both the sexes. The intakes were higher in the younger age group (60-69 years) than in the other age groups, in both the sexes, though it was statistically significant only in females ( $p<0.01$ ). The intakes among non-elderly adults were higher than the elderly adults. The median energy intakes of males (2080 Kcal) and females (1689) were less than the RDI. (RDI for energy among elderly was calculated according to their body weights). The mean intakes of energy, which were in marginally higher than the medians for male and females were 2167 and 1764 kcal. The mean intakes decreased with increasing age. The consumption of iron in both the sexes was lower than the RDI. The average consumption of calcium was, however more than the RDI $(400 \mathrm{mg})$ in both the sexes.

The intake of vitamin A was below the RDI ( $600 \mu \mathrm{~g}$ ) in all age groups. The median intake was more in males ( $168 \mu \mathrm{~g}$ ) than females ( $137 \mu \mathrm{~g}$ ). The intakes increased with increasing age among the males. The median intake of thiamin was marginally lower than the RDI (Males: 1.2 mg and females: 1.0 mg ). In the case of non-elderly adults the intakes were more than the elderly (males: 1.4 mg and females: 1.2 mg ). The consumption was more among younger age groups of the elderly in both the sexes.

The consumption of riboflavin was less than the RDI in all three age groups. Mean intakes were significantly different between ages in females ( $p<0.05$ ). The riboflavin intake among non-elderly adults was comparable with the elderly in both the sexes. The mean intake of vitamin $C$ was more than the recommended level of 40 mg for males ( 46 mg ), while it was comparable in females ( 39 mg ), in each age group. The median intakes were, however, less than RDI.

### 3.2.3 Distribution of Nutrient Intake by per cent of RDI

Distributions of individuals according to intake of major nutrients as per cent of RDI are presented in Table 7.

About $65 \%$ elderly population consumed more than the RDI of energy. The percentage consuming more than RDI were slightly more among the males (71\%) than in females ( $60 \%$ ). The corresponding figures for the non-elderly adults were $52 \%$ and $64 \%$ respectively. It may be noted that while the RDI of elderly is based on actual weights. A negligible proportion of elderly (1.4\%) consumed energy below $50 \%$ of RDI. The consumption of protein was less than $50 \%$ of RDI in about $2 \%$ of the elderly. As in the other age groups, the micronutrient intakes were inadequate.

The intake of vitamin A was very unsatisfactory. In about 59\%, the intakes were less than $30 \%$ of RDI, while only $13 \%$ consumed more than the RDI. The intakes of riboflavin were more than RDI in only $11 \%$ of individuals, while $5.2 \%$ were consuming $<30 \%$ RDI (Table 7). About $16 \%$ consumed less than $50 \%$ of RDI of thiamin. In about $38 \%$ the intakes were more than RDI.

### 3.2.4 Protein Calorie adequacy status

- The protein and energy requirement curves are assumed to follow gaussian distribution, with a coefficient of variation of $15 \%$. The ICMR Expert Committee suggested mean requirements of energy for different ages, whereas in the case of protein, the RDI corresponded to Mean $+2 S D$ of actual requirements. The

Individuals with less than Mean - 2 SD of requirements of energy/protein were categorized as energy/protein inadequate.

Protein-Calorie adequacy status was observed in a large proportion of elderly (Male: $90 \%$; Female: $82 \%$ ). As the age advanced the inadequacy status also increased in both the sexes.

### 3.3 NUTRITIONAL STATUS

The mean, median and SDs of anthropometric measurements according to age, sex and period of survey are presented in Tables 8 to 10. The mean heights of elderly decreased in both the sexes, as the age advanced. However, such a trend was noticed only among males.

The nutritional status of the elderly was assessed based on Body Mass Index (BMI). It is the ratio of weight in kgs, and square of height in meters. The mean BMI was higher in the younger age group of males, while in the case of females it was higher in the older age group. The elderly were grouped into different nutritional grades using James ${ }^{6-8}$ Classification, was given below.

| BMI | Nutritional Grade |
| :---: | :--- |
| $<16.0$ | III degree CED |
| $16.0-17.0$ | II degree CED |
| $17.0-18.5$ | I degree CED |
| $18.5-20.0$ | Low normal |
| $20.0-25.0$ | Normal |
| $25.0-30.0$ | I degree obesity |
| $>30.0$ | II degree obesity |

The prevalence of Chronic Energy Deficiency (CED) (BMI <18.5) was relatively more among males (53.5\%) than in females (49.4\%). It was observed that the proportion of CED increased with increasing age among males, while it was the lowest among the females of 80 years and above. This may be due to the common observation that, in general, BMI is higher in females than males. The prevalence of obesity (BMI > 25.0) was $4.2 \%$ in males, and $7.7 \%$ in females (Table-10 \& Fig.3a, $3 b \& 4 a, 4 b)$.

In the case of non-elderly adults, the prevalence of CED was lower than the elderly in both the sexes (Males: 44.2\%; Females: 46.8\%).

## 4. TIME TRENDS IN FOOD AND NUTRIENT INTAKES

The average intakes of different foods are presented in Tables 11 \& 12. The mean intakes of all foodstuffs were higher in 1996-97 than those of 1975-79, except with respect to pulses in case of males and females and roots \& tubers among females. The intakes of GLV, millets, fish and foods continued to be negligible at both points of time.

The median intakes of nutrients among the elderly were higher in 1996-97 than those of 1975-79 except with respect to thiamin in both the sexes. (Table13 \& 14). The medians of most of the nutrients, except iron and niacin were statistically significantly different between periods ( $\mathrm{p}<0.05$ ).

A comparison between the two periods revealed that the extent of CED declined from about $62.3 \%$ in 1975-79 to $53.5 \%$ in 1996-97 among the males and from $63.8 \%$ to $49.4 \%$ among the females. There was a concomitant increasing trend in the proportion of normal, overweight / obesity between 1975-79 and 1996-97 (Table 15).

## 5. EFFECT OF SOCIO-ECONOMIC STATUS

### 5.1 BODY MASS INDEX

A comparison of the prevalence of CED (BMI <18.5) among elderly males and females between the two periods indicates that there was evidence of reduction in the prevalence in 1996-97 as compared to 1975-79 among the elderly belonging to SC + ST communities, illiterates, those living in kutcha houses and among landless (Table-16). The distribution of the individuals according to BMI is presented in the (Tables 17 to 22). The proportion of CED (BMI: < 18.5) was much higher among the elderly belonging to SC+ST communities (64.6\%), than other communities (36.5\%) (Table-17). On the other extreme the extent of overweight was much higher in others (7.1\%) than among the SC+ST ( $2.6 \%$ ). There were no differences in grade III CED between nuclear and joint families (16.6\%). (Table-18). CED was higher in illiterates (57.3\%) than among the literates (41\%) (PO.001) (Table-19).

There was an association between BMI and family size ( $\mathrm{p}<0.05$ ), though the differences were small. The prevalence of CED with III degree was more among the larger families (18.1\%), where the mean family size was seven and above than smaller families (15.4\%) ( $\mathrm{P}<0.05$ ) (Table-20). The extent of CED was higher among the elderly living Kutcha houses (60.0\%) was almost twice as those residing in pucca houses ( $35 \%$ ). The proportion of normal ( $13.1 \%$ ) was also similarly higher in pucca houses than those living in other types of houses $(p<0.05)$ (Table-21).

As expected, the elderly of the labourers families were at a disadvantage with higher prevalence of CED as compared to agriculturist's (52\%) and Others (47\%) ( $p<0.001$ ) (Table-22). The prevalence of CED was highest (53.4\%) among the elderly belonging to the households who had no land. The extent of CED was the lowest among individuals who had owned more than 10 acres ( $\mathrm{p}<0.001$ ) (Table-23).

Table 16 PREVALENCE (\%) OF CED (BMI < 18.5) AMONG ELDERLY ACCORDING TO HOUSEHOLD SOCIOECONOMIC CHARACTERISTIC AND PERIOD OF SURVEY - SEXES POOLED

| Household Particulars | Percent of BMI < 18.5 |  |

## TIME TRENDS

## NUTRITIONAL STATUS

## ANTHROPOMETRY

- $54 \%$ of males and $49 \%$ of females had CED (BMI <18.5), white about $42 \%$ of males and $43 \%$ of females were normal
- The extent of CED declined from 63\% in 1975-79 to 53\% in 1996-97

### 5.2 FOOD INTAKES

The average daily intakes of various foods and nutrients were compared according to socio economic parameters, such as community, type of house, type of family, occupation of head of HH and landholdings, the results are presented in Tables 24-30.

### 5.2.1 Community

The consumption of most of the food stuffs, except cereals \& millets and GLV, was lower among elderly of SC \& ST community ( $\mathrm{P}<0.05$ ) (Table 24).

### 5.2.2 Type of Family

The average intakes of majority of foods were comparable among the elderly of nuclear families and those from the joint families (Table 25).

### 5.2.3 Type of house

The type of house is considered as an index of socio economic status. The current intakes of almost all the food stuffs were higher among the elderly who were staying in pucca type of houses except for cereals \& millets ( 448 g ) and GLV (20 g)
(Table 26). The consumption of mean food stuffs, except pulses, other vegetables and roots \& tubers and fats \& oils were different between type of houses in all the foods ( $\mathrm{p}<0.05$ )

### 5.2.4 Land holdings

The consumption of pulses, other vegetables, milk \& milk products, fats \& oils and sugar \& jaggery was higher among the households, which had more than 10 acres of land. Significant differences were observed between the elderly of the households with different sizes of land holdings with respect to cereals, pulses, nuts \& oil seeds, fish and milk and milk products ( $\mathrm{p}<0.05$ ) (Table 27).

### 5.2.5 Occupation

The consumption of all food stuffs, except cereals \& millets (433 g) and GLV (23 g), was lower among the labourers compared to those who were engaged in agriculture and services. The mean intakes of majority foods except fruits, other flesh foods and sugar \& jaggery were significantly different between occupational groups ( $p<0.05$ ) (Table 28).

### 5.2.6 Family size

The consumption of cereals \& millets ( 436 g ) and pulses ( 36 g ) was higher among the elderly living in households with family size 7 or more compared to small families ( $\leq 4$ members). However the consumption of milk and milk products was higher among small families (Table 29).

### 5.2.7 Literacy Status

Literacy of the head of the household seems to play an important part in determining food intakes. Among the illiterates the current consumption of cereals \& millets (421 g), and GLV (17 g) was higher. However, among the illiterates the consumption of milk, fish and other flesh foods, fruits, other vegetables and nuts and oil seeds was lower than those of literate. It was also observed that the mean intakes of all the foods except GLV, other flesh foods and sugar \& jaggery were significantly and positively associated with educational status of the head of the household ( $p<0.05$ ) (Table 30).

### 5.3 NUTRIENT INTAKES

The average daily intakes of various nutrients according to socio-economic parameters were given in Tables 31-38.

### 5.3.1 Community

There were no perceptible differences in the nutrient intakes between the households of SC \& ST communities and others. The mean intakes of calcium, iron and riboflavin were higher in others than among SC \& ST ( $\mathrm{p}<0.05$ ) (Table-31).

### 5.3.2 Type of family

The intakes of majority of nutrients, though were more among the nuclear families than those in joint families, were not significantly different between type of families ( $\mathrm{p}>0.05$ ) (Table 32).

### 5.3.3 Type of House

The consumption of nutrients like energy, iron, vitamin A and niacin was surprisingly more among individuals who are staying in kutcha type of houses compared to those individuals who are staying in semi-pucca and pucca type of houses (Table 33).

### 5.3.4 Land holdings

The nutrient intakes were more among the individuals who had land holdings 10 acres and above (Table 4).

### 5.3.5 Occupation

It was observed that the consumption of all the nutrients except that of vitamin A and vitamin $C$ was more among the individuals where the occupation of head of the households was agriculture. The intakes of a majority of nutrients, except vitamin A and vitamin $C$ were significantly different ( $\mathrm{P}<0.05$ ) between occupations (Table 35).

### 5.3.6 Family size

Surprisingly the consumption of nutrients like protein (53 g), energy (2025 Kcal), iron ( 25 mg ) and niacin ( 13.1 mg ) was more among the families with 7 or more members, compared to smaller families. This may be because of higher number of earning members. The mean intakes of calcium, iron, thiamin and vitamin ' C ' were statistically significant between different family size (Table 36).

### 5.3.7 Literacy

The mean intakes of majority nutrients except iron ( 24.1 mg ), vitamin A (295 $\mu \mathrm{g}$ ), thiamin ( 1.1 mg ) and niacin ( 12.1 mg ) were more among literates than those among the illiterates. The mean intakes of protein, calcium, iron, thiamin, riboflavin, and vitamin 'C' were significant ( $p<0.05$ ) by literacy status (Table 37).

### 5.3.8 Per capita Income

The consumption of most of the nutrients were more among the individuals who had per capita income of more than Rs. 3000 (Table 38).

Time trends in socio-economic status versus food and nutrient intakes and nutritional status are presented in Annexures 1-14.

## SOCIO ECONOMIC STATUS Vs. FOOD AND NUTRIENT INTAKE

- Higher intakes of cereals and GLV reported in SC \& ST communities.
- Higher intakes of income-elastic foods observed among HHs having more than 10 acres.
+ Intakes of Energy, Iron, Vitamin A and Niacin were more in households living in kutcha houses.
- Intakes of Protein, Energy, Iron and niacin were more in households with large family size.

## 6. CONCLUSIONS

The objective of the study was to assess the current diet and nutritional status of the elderly utilizing the data collected by NNMB during 1996-97 and to study the time trends since 1975-79. This information could perhaps be considered as the first large database on diet and nutritional status of the elderly in India.

The results of the study indicated that, the overall intake of various foods except cereals \& millets was less than RDI in males. Similarly, the average intake of all the nutrients except calcium, thiamin and Vitamin C was less than RDI.

The consumption of foods increased during 1996-97 except in pulses from that observed in 1975-79. The prevalence of CED decreased over the period, with a concomitant increase in the prevalence of overweight among males and females. There is however, a need to conduct comprehensive surveys including information on diet related chronic diseases and behavioral and psychosocial aspects, in addition to diet and nutritional status.

## ACKNOWLEDGEMENTS

We wish to convey our thanks to Dr.A.Laxmaiah, Dr R.Hari Kumar and Dr.M.Vishnuvardhana Rao, Senior Research Officers; Dr.N.Ariappa, Mr.Ch.Gal Reddy, Mr.K.Mallikharjuna Rao and Mr.B.Surya Prakasham, Research Officers; Mr.Sharad Kumar and Mr. M.Ravindranath, Technical Research Officers; Ms.M.Uma Nayak and Ms.K.Damayanthi, Nutritionists for their help during analysis.

We also thank Mr.P.Satish Babu, Mr.G.Govinda Rajulu, Ms.K. Shyamala, Ms.Vani Vijayaratnam, Ms.G.Madhavi and other staff for their technical help. Our thanks are also due to Mr. G. Hanumantha Rao and Ms. G. Prashanthi for their secretarial help.

## SUMMARY

The report presents the results of the analysis of 24-hour dietary recall data on individuals of different ages, collected by the National Nutrition Monitoring Bureau. The current dietary status was assessed based on the data collected in 1996-97 as a part of second repeat survey in the same villages, which were visited in 1975-79. In addition, time trends in the food and nutrient intakes were assessed by comparing the above two sets of data, collected about two decades apart. The data of about 15100 individuals in 1996-97 and 17938 in 1975-79, belonging to different age, sex, physiological and physical activity groups formed the material of the analysis.

The results indicated that there was considerable variation in the intakes of both foods and nutrients, with a very high coefficient of variation, ranging from about $40 \%$ to more than 100\%. The variation was particularly high in the intakes of foods like millets, green leafy vegetables, other vegetables, milk and milk products and fats and oils. Even in the case of nutrients, the variation was high especially in the case of micronutrients, fat, and relatively to a lesser degree in the case of energy and protein. The median intakes of food and nutrients, in general, were below the RDI. There were no differences between the intakes of non-pregnant \& non-lactating (NPNL) females and pregnant women, despite the increased requirements due to pregnancy and lactation. About $30-40 \%$ of the individuals in different age groups had cereal intakes comparable to RDI. The children appeared to be worse off and about $10 \%$ had cereal-millet intakes less than half of RDI. About 83-90\% of individuals consumed less than 30\% of RDI of GLV.

About 13 to 55\% of individuals consumed energy more than or equal to RDI. Only about $11 \%$ of the population were consuming adequate amounts of Vitamin A, and $50-70 \%$ had intakes less than $30 \%$ of RDI. Iron consumption was inadequate in more than $90 \%$ of the individuals in almost all the age groups. There was an increase in the consumption of mean cereal intakes in all age groups in 1996-97, except in children of 1-3 years of age, as compared to those of 1975-79. The changes in the consumption of pulses and GLV were negligible (<5\% of 1975-79 intakes). Median test revealed that there were no significant differences, between the periods, in the intakes of energy, vitamin $A$ and fat in 1-3 year old children. However, there was significant improvement in the intakes of the above nutrients in the other age groups. But, in the case of iron, there were significant changes only in the intakes of adult males, adult females (NPNL) and lactating women. These results, based on comparison of median intakes of individuals, are different from those reported earlier, which did not reveal any changes in the mean intakes of foods and nutrients of households

## 1. INTRODUCTION

The National Nutrition Monitoring Bureau (NNMB) has been continuously collecting information on diet and nutritional status of the communities in 10 States since the year 1972. Every year, the bureau collected information in selected households on dietary intakes at the household level using one-day weighment method, and of individuals of different ages by 24 -hour dietary recall method. While the results of household diet surveys have been reported in the annual reports of the NNMB, the information on individual intakes has not been regularly presented, particularly since the year 1988. In this report, the results of analysis of data on 24 hour recall diet survey, conducted in 8 States, to assess the dietary pattern of individuals of different ages and physiological groups obtained in 8 States are presented.

### 1.1 Objectives

i) To assess the current food and nutrient intakes of individuals of different physiological and age groups in the States surveyed.
ii) To assess the time trends, if any, in the dietary pattern, by comparing the data collected in 1996-97 on dietary status of individuals with that from the same villages which were surveyed during 1975-79.

## 2. MATERIALS AND METHODS

The current dietary status was assessed based on the data collected during 1996-97 as a part of second repeat survey ${ }^{1}$. This survey was carried out in the States of Andhra Pradesh, Gujarat, Karnataka, Kerala, Maharashtra, Orissa and Tamil Nadu. A total of 120 villages were selected for survey in each State, of which 90 were from those covered in 1975-79 and the remaining were new. In each village, 20 HHs were selected from which 10 were selected for diet survey. In five of these $10 \mathrm{HHs}, 24$-hour recall diet survey was done on all the members.

### 2.1 Analysis

The mean, median and SD were calculated for the data, collected as a part of second repeat survey. The data collected in 1975-79 were similarly analysed and compared with that collected in 1996-97 to assess time trends. Moving averages were calculated to pool data collected during 1988-1992.

Distribution of individuals of different age and sex groups according to food and nutrient intakes expressed as percentage of Recommended Dietary Intakes (RDI)2,3 was calculated.

## 3. RESULTS

### 3.1 Sample

The sample covered in different ages in different States according to the period of survey is presented in Table-1. During 1996-97, about 15094 individuals belonging to different age and physiological groups were surveyed, while 17938 individuals were covered during 1975-79.

Table 1 SAMPLE COVERAGE ACCORDING TO AGE, SEX AND PERIOD OF SURVEY

| Age | Year of Survey |  |
| :--- | :---: | :---: |
|  | $1996-97$ | $1975-79$ |
| $1-3$ Pooled | 1313 | 1764 |
| $4-6$ Pooled | 1336 | 2089 |
| $7-9$ Pooled | 1187 | 1859 |
| $10-12$ boys | 522 | 801 |
| $10-12$ girls | 524 | 725 |
| $13-15$ boys | 404 | 528 |

| Pregnant | 908 | 924 |
| Lactating |  |  |
|  | 15094 | 17938 |

| COVERAGE |  |  |
| :---: | :---: | :---: |
| DIET SURVEY | 1975-79 | $1996-97$ |
| • | Households : 6497 | 6551 |
| - | Individuals : 17,938 | 15,100 |

### 3.2 Food Intakes

The mean, SD and median of intakes of most of the foods were below the RDI levels (Tables-2 to 4). The coefficient of variation of all food intakes was very high. The median values were less than those of means.

Cereals (rice/wheat) were the staples in all the States surveyed. The mean intakes of millets ranged from about 31 g in 1-3 year old children to 120 g in adult males. The median intakes however revealed that less than $50 \%$ of the individuals were consuming millets. The intakes of protective foods like GLV, fruits, fats and oils, and milk and milk products were woefully inadequate in almost all the ages.

NPNL : Non Pregnant \& Non Lactating

## FOOD INTAKES OF INDIVIDUALS

- Intake of most of the food was below the RDI in all ages, except adults.
- Protective foods like GLV, fruits, fats and oils and milk and milk products were inadequate in almost all ages.
- Half of the individuals among different age groups the intake of pulses was grossly less than $30 \%$ of RDI.
- Pregnant and lactating women did not consume any additional quantities of foods over and above the NPNL.

### 3.2.1 Nutrient Intakes

The energy consumption among adults was comparable to RDI. Interestingly, in the case of females there was no difference between the intakes of non-pregnant \& non-lactating (NPNL) females and pregnant women despite the increased requirements due to pregnancy. (Tables- 5 to 7). Though, in general, the median nutrient intakes in all the age groups were below the RDI, these were particularly poor in the case of micronutrients like iron and vitamin A. It may be pointed out that food iron values have been revised and, as per these the median iron intakes were $50 \%$ of RDI, contrary to the earlier apparently normal intakes. In this report, iron intakes according to the old as well as revised values are presented.

Table 5 AVERAGE DAILY INTAKE OF NUTRIENTS BY AGE GROUP

| Age Groups (Years ) |  |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## NUTRIENT INTAKES OF INDIVIDUALS

- Median intake of all the nutrients in all the ages was below the RDI.
- Intakes were very poor in case of micronutrients like iron and vitamin $A$ in all ages.
- $50 \%$ of individuals had protein calorie adequacy status.

### 3.3 Distribution of intakes as \% RDI

### 3.3.1 Foods

The distribution of individuals of different age and sex groups according to intakes of different foods expressed as percent RDI is presented in Tables $8 \& 9$ and proportion of Households consuming various foods below $70 \%$ of RDI are shown in Figs. $1 \& 2$. In general, about $30-40 \%$ of the individuals in different age groups consumed more than or equal to RDI of cereals. The proportion of individuals consuming more than RDI was higher among adult males and females, and also among those involved in moderate physical activity. The children however, appeared to be worse off, as about 10\% had poor intakes (<50\% of RDI) of cereals and millets. With respect to pulses, while the adults of both the sexes had adequate intakes, only $10-18 \%$ of children had intakes comparable to or more than RDI. The consumption of pulses was so poor that about 40-50\% of individuals in different groups consumed less than $30 \%$ of RDI of pulses. The consumption of GLV was woefully inadequate. The proportion of individuals of different age groups having adequate GLV intake varied from $5 \%$ in 1-3 years age group to $14 \%$ in adult males. The intakes among females were $4-5 \%$ of RDI. About 83-90\% of individuals consumed less than 30\% of RDI of GLV.

Consumption of other vegetable was also much less than the RDI in almost half of the population surveyed. Milk consumption was unsatisfactory in almost 70\% of the individuals, particularly in young children. Over 75\% of preschool children consumed less than $30 \%$ of RDI of milk. The pregnant and lactating women did not consume any additional quantities of milk over and above those of NPNL. Only 15\% of individuals had fat intakes comparable to RDI. About 50\% of preschool children had low intakes of sugar ( $<30 \%$ of RDI). The consumption of flesh foods though was low in all the ages, in general, in the State of Kerala the intake of fish and meat was better than that in all the other States.

### 3.3.2 Nutrient Intakes

The distribution of individuals according to percent of RDI for different nutrients is presented in Tables-10 \& 11 and proportion of Households consuming various Nutrients below 70\% of RDA are shown in Figs. 3 to 5.

Only 12-24\% of individuals between 1-6 years and 13-15 years had adequate energy intakes. In the other ages 13 to $55 \%$ of individual were consuming more than or equal to RDI of energy. Protein adequacy was also observed in about a half of the individuals. Only a very small proportion (11\%) of the population was consuming adequate amount of vitamin A. The intakes were so poor that about $50-70 \%$ had intakes less than $30 \%$ of RDI. Iron consumption was inadequate in more than $90 \%$ of the individuals in almost all the ages. Calcium intake was also very low in most of the age groups, especially in the children of 1-3 years, pregnant and lactating women.

The mean intake of foods and nutrients for 1988-92 (moving average) are given in Tables 12 \& 13. The consumption of all the foods was less than RDI in all the age groups. The nutrient intakes were, in general less than RDI.

## 4.TIME TRENDS

### 4.1 Food Consumption

The changes in mean intakes between 1975-79 and 1996-97 are presented in Tables 14 to16. There was an increase in the consumption of mean cereal intakes in all the age groups, except in 1-3 years of age. The increase ranged from about 12 g (7\%) in 4-6 year old children to about $104 \mathrm{~g}(25 \%)$ in pregnant women. The median intake of millets did not show any change (zero), indicating that about a half of them did not consume millets at all at both points of time. The changes in pulse consumption were negligible. Like the millets intakes, the median intakes of GLV at both time points was poor with at least $50 \%$ of them not consuming GLV at all at both points of time. There was an increasing trend in the consumption of the mean intakes of milk and milk products, though the magnitude of increase was small (<20 $\mathrm{g})$. It was interesting that the milk consumption showed an increasing trend in all age groups except 1-3 years and pregnant women, though these were much below the RDI.

NPNL: Non Pregnant Non Lactating

## TIME TRENDS

## FOODS INTAKE :

- Increase in consumption of cereals was observed in all ages.
- Intakes among pregnant and lactating women were marginally increased over a period of time.
- A marginal increase was observed in consumption of qualitative foods such as GLV, Fruits, Milk and sugar \& Jaggery.

### 4.2 Nutrient Consumption

As already indicated, the coefficient of variation of nutrient intakes was high and ranged from about $40 \%$ in energy to about $70 \%$ in total fat. Hence, to assess the time trends, the median intakes obtained in 1996-97 among different groups were compared with those of 1975-79. Interestingly, the results are different from those reported earlier based on the mean intakes of one day weighment family diet survey, which had indicated no change in dietary consumption. In general, there was an increasing trend with respect to protein ( 1 g in $4-7$ years to 8.9 g in lactating women) and energy ( 36 Kcal in $1-3$ years to 446 Kcal in lactating women). Similar changes were noticed in fat ( 1.4 g in $1-3$ years to 7.4 g in NPNL) and vitamin A ( $5 \mathrm{\mu g}$ in $1-3$ years to $64 \mu \mathrm{~g}$ in 16-18 years old girls). The results are presented in Tables 17 to 19 and Figs. 6 to 9 . Median test revealed that there is significant improvement in the intakes of vitamin A and fat in all age groups except 1-3 year children and pregnant women. Energy intake was improved in all age groups except 1-3 year children (Table 20).

## 5. COMMENTS

The report presents intakes of individuals of different ages and physiological status. The variation in food and nutrient intakes was very high, making comparison of mean intakes different. In general, the food and nutrient intakes were much below the RDI. Specifically, the intake of protective foods like pulses, GLV, flesh foods and milk \& milk products was unsatisfactory. In fact, the variation in the intakes was large, indicating that the percent of individuals consuming these foods was small. Similarly, the consumption of micronutrients were poor. For example, only about $10 \%$ of the individuals were consuming adequate amounts of vitamin A , iron or riboflavin. The results indicated that, by and large, the improvements in the median intakes are at variance with those reported earlier based on family diet survey. While improvement in individual intake is in tune with improvement in nutritional status, there is a need to examine the reasons for the differences between household diet survey and 24 hour recall diet survey.
